ZEPTO SALES ANALYSIS

Power BI Project Report and Visual Insights

1. INTRODUCTION

The Zepto Analysis dashboard was developed in Power BI to explore product sales, revenue, pricing, discounts, category performance, and stock availability. It combines headline KPI cards with category comparisons, product rankings, and price-related visuals. The report is intended to help users compare product categories and identify items that may warrant closer business review.

2. DATA AND DASHBOARD OVERVIEW

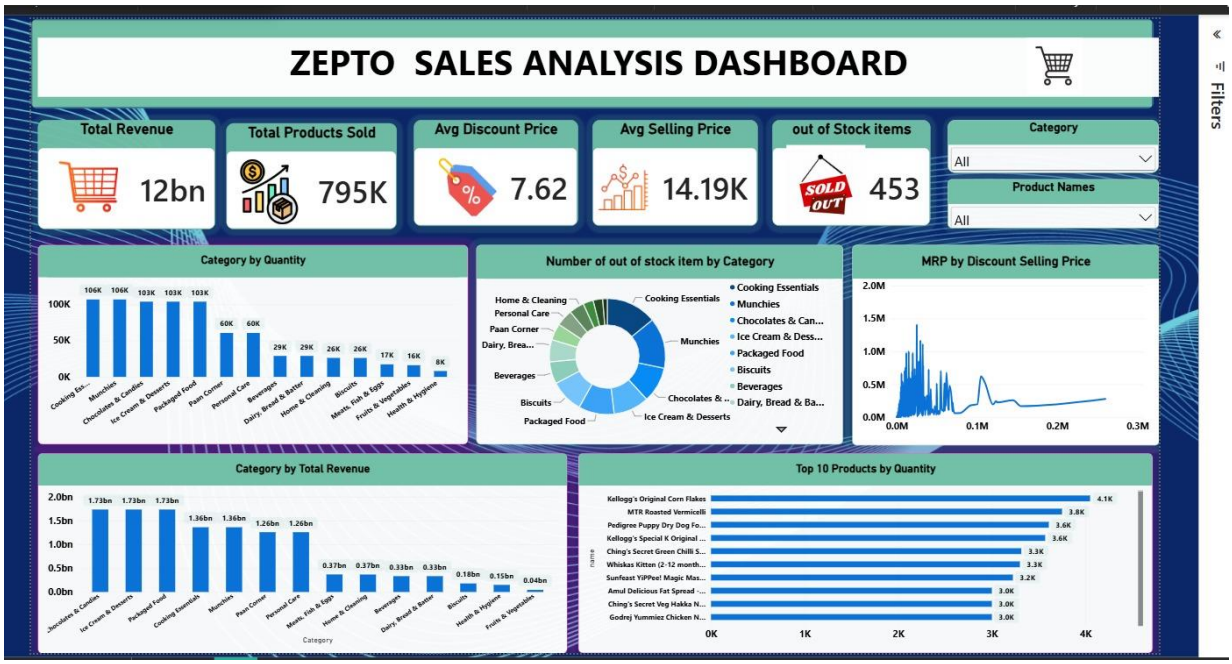

The uploaded Power BI report uses a table named Sheet1. The visible fields referenced by its visuals include product name, category, quantity, MRP, discounted selling price, discount percentage, total revenue, and an out-of-stock item measure. Category and product-name slicers are included to support focused exploration.

The report contains KPI cards for Total Revenue, Total Products Sold, Avg Discount Price, Avg Selling Price, and the number of out-of-stock items. The visual layout also includes a category-based donut chart for out-of-stock items, a category-by-quantity column chart, a comparison of MRP and discounted selling price, a category-by-revenue chart, and a top-10-products-by-quantity bar chart.

3. OVERALL DASHBOARD AND KPI INSIGHTS

The KPI cards provide a high-level view of sales and inventory-related measures. They are useful for understanding overall performance before drilling down into individual categories or products.

- Total Revenue: summarises the revenue measure used in the dashboard.
- Total Products Sold: uses the quantity field to represent product volume.
- Avg Discount Price: presents the dashboard's average discount-related price measure; confirm the exact calculation before interpreting it as an average discount amount.
- Avg Selling Price: presents the average discounted selling price measure.
- Out-of-stock items: counts the out-of-stock measure used by the report.

The uploaded dashboard definition does not expose the current rendered KPI values in a form that can be verified here. Therefore, this report describes the measures and comparisons rather than assigning unverified numeric results.

4. DETAILED INSIGHTS FROM THE VISUALS

4.1 Category by Quantity

- The column chart compares quantity across product categories, helping identify categories that contribute more to the recorded sales volume.
- Use this chart alongside revenue: a category with high quantity may not generate the highest revenue if its products have lower selling prices.

4.2 MRP and Discounted Selling Price

- The line chart compares MRP with discounted selling price across categories, making price differences and discounting patterns easier to inspect.
- Large gaps between MRP and discounted selling price may indicate stronger markdowns, but the discount percentage and price fields should be checked for consistent units and calculations.

4.3 Category by Total Revenue

- The revenue chart compares total revenue across categories and can help highlight categories with stronger revenue contribution.
- Revenue should be interpreted together with quantity and selling price, since sales volume alone does not explain revenue performance.

4.4 Top 10 Products by Quantity

- The bar chart ranks the top ten products by quantity, allowing the most frequently sold products to be identified quickly.
- High-volume products may be candidates for stock monitoring, but quantity alone does not establish profitability or margin.

4.5 Out-of-stock Items by Category

- The donut chart distributes the out-of-stock item measure across categories, showing where recorded stock-outs are concentrated.
- A category with a larger share may deserve inventory review; however, the result should be compared with the total number of products in each category to avoid misleading comparisons.

5. CONCLUSION AND RECOMMENDATIONS

The Zepto Power BI dashboard brings sales, pricing, product quantity, category revenue, and out-of-stock information into one report. Its KPI cards provide a summary, while the category charts and product ranking support more detailed comparisons. Together, these visuals can help users investigate sales mix and possible inventory concerns.

- Validate the DAX definitions for Total Revenue, Total Products Sold, average price measures, and out-of-stock counts before using the KPIs for formal reporting.
- Compare revenue and quantity together, and review product-level selling prices before concluding which categories perform best.
- Compare out-of-stock counts with category size and sales demand before prioritising replenishment.

The report is descriptive. Because the uploaded Power BI package does not provide verifiable rendered values in the extracted visual metadata, numerical claims and rankings beyond the visual titles have not been invented.
